2.2.2.3. Influence of commercial systems on private needs

As indicated above, utilities do use commercial cellular type systems (i.e., cellular, PCS or ESMR) to augment their voice systems. Commercial data systems are also employed. While these services can add to utility communications, it is highly unlikely that they will be able to serve as a replacement for the private dedicated utility system.

This study accounted for commercial system usage. As in the PSWAC study, it was assumed that approximately 10% of spectrum requirements would be satisfied by commercial systems in the future.

2.2.3. Restructuring of the Electric Utility Industry in the United States

Driven largely by industrial customers, electric utility restructuring is already unfolding in a number of states. Restructuring is often labeled "deregulation," which is a misnomer because there will still be a great deal of regulation when the smoke clears. It is perhaps better labeled "reregulation," since regulation will be redesigned and redistributed, but still pervasive.

2.2.3.1. What is Restructuring?

Restructuring is essentially the transition from "vertically integrated" monopolistic electric service to competitive service. To discuss restructuring, one must first look at how a traditional utility is structured.

Generally, there are four functional units within an electric "utility":

- 1. Generation;
- 2. Transmission;
- 3. Distribution:
- 4. The Customer Information Unit.

The generation unit converts some resource (e.g., oil, coal, nuclear fuel, air flow, water flow, etc.) into electrical energy. Electric power does not generally lend itself to efficient storage, so the amount of generation will be based upon expected demand.

The <u>transmission</u> unit carries the electricity that has been generated to areas where it will be utilized. Often the source of generation, a dam for example, is far removed from the end user. To effectively carry power long distances, it is necessary to use high voltage transmission lines.

The <u>distribution</u> side of the utility lowers the transmission voltage to practical usable voltages and delivers the electricity to the end user.

The forth category, the <u>customer information unit</u>, is the interface with the customer providing metering and billing for the use of the electricity.

Prior to restructuring, the above operational units usually fell within the control of a single company, i.e., the "utility." In a restructured environment however, some, if not all, of these constituent parts will be separated and operated by independent entities. Additionally, new entities may be created. For example, California has developed a system that includes an Independent System Operator (ISO). This non-profit company will be employed as an independent manager of the transmission network. It will ensure equal access to the transmission grid by all generators. A power exchange (PX) will also be employed in the California system. The PX will act as a broker for bulk power.

To get a better sense of California's restructuring plan, visit the California Energy Commission's Restructuring Web site: http://www.energy.ca.gov/restructuring. Another comprehensive Web site on restructuring is the U.S. Energy Information Administration's Restructuring site. The URL is: http://www.eia.doe.gov/cneaf/electricity/page/at a glance/restruct.html

2.2.3.2. How will Restructuring impact telecommunications?

Telecommunications will still be an integral part of utility operation after restructuring has taken full effect. It will still be necessary to reliably control the vast network of deployed electric networks. In fact, a greater need for wireless communications may exist due to reduced staff. As the industry becomes decentralized and power sources become increasingly dispersed, precision control systems will become critical. Additionally, automated processes and remote access will become more prevalent. These will be practicable only to the extent that communications infrastructure can support these applications.

To survive in a competitive environment, the new utility will need to keep costs to a minimum. As a result, some communications requirements will likely be outsourced. However, the utility will still require extensive private communications to support its critical infrastructure.

3. The Utilities Spectrum Assessment Taskforce (USAT) Project

3.1. Surveys

3.1.1. Steering Committee Survey

A detailed survey was developed for steering committee members to complete. After formally answering the questions on this survey, steering committee members were able to determine the shortcomings and ambiguities of the instrument. This feedback was then applied to the final survey.

3.1.2. Final Survey

The final survey was formulated using comments from those who had taken the steering committee survey. It was to be more user friendly, shorter and generally more to the point than the steering committee survey. Once completed, it was forwarded to UTC's Wireless and Frequency Coordination Sections. Additionally, it was sent to a number of additional water utilities with the help of American Water Works Association (AWWA). A total of 94 surveys were completed and returned to UTC. Charts indicating the demographics of the respondents and some highlights of the survey results follow:

. 1

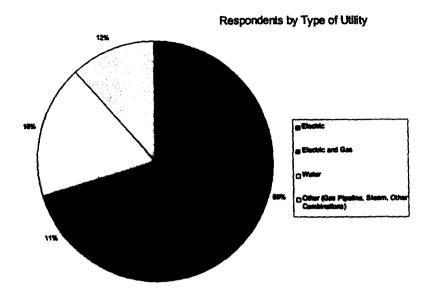

Figure 3

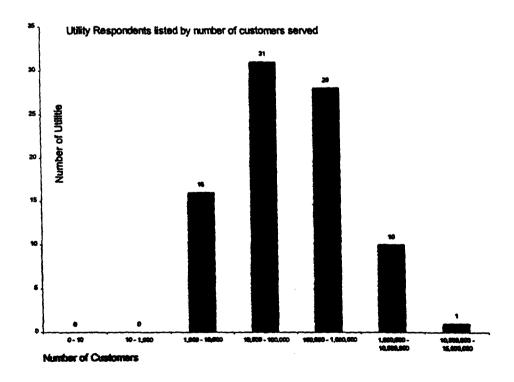

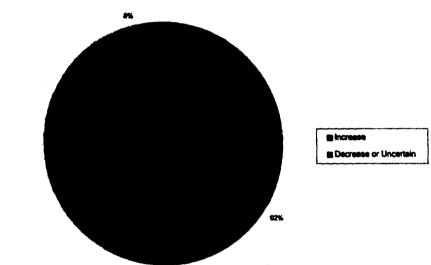

Figure 4

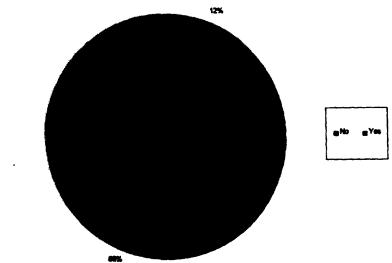

As shown above, over half of the respondents were electric utilities. Additionally, most of the respondents serve between 10,000 and 1,000,000 customers.

Figures 5 and 6 below indicate that an overwhelming majority of the respondents to the survey believe that there will be an increase in the use of wireless applications and that they will need additional spectrum to accommodate these applications.

Answers to "In general, do you foresee an overall increase or decrease in the use of privately owned, internal wireless applications (voice, data, video, etc.) in your company in the next ten wears?"

Figure 5

Answers to "In the next ten years, do you anticipate needing additional spectrum to meet internal communications needs (voice, data, video, etc.)?"

Figure 6

The following figures show that there will be a considerable demand for wireless wide band data and wireless video. These technologies are gaining momentum and should be nearing maturity by the middle of the next decade.

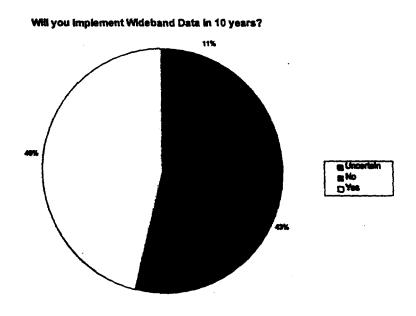

Figure 7

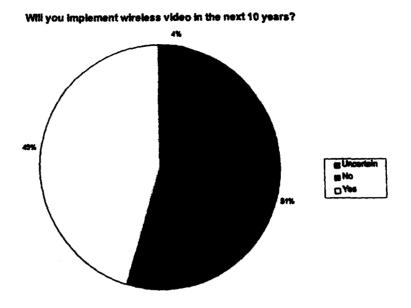

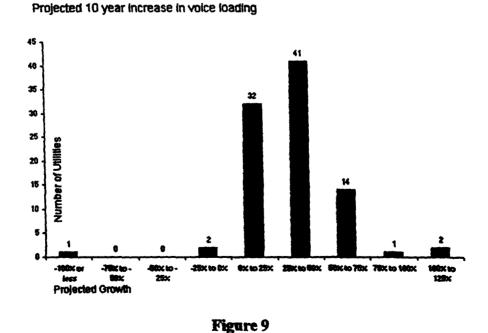

Figure 8

Figure 9 below shows that almost all of the respondents predict an increase in voice loading, and many predict a substantial increase.

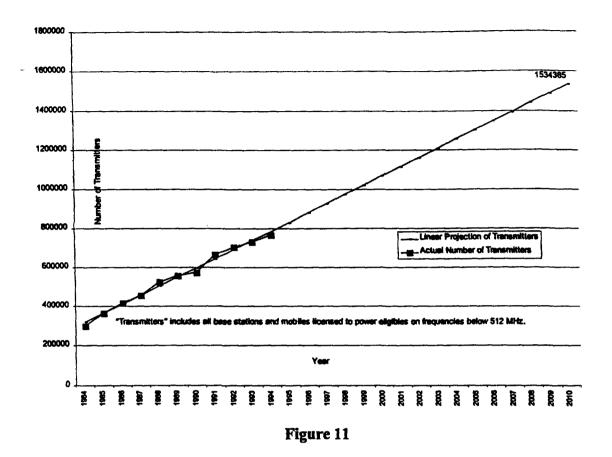

3.2. Linear Projection of Spectrum Needs from Historical Data

• 🔨

As further input into the process, a simple extrapolation of license demand was performed. Licensee data was taken from FCC reports and extrapolated to the year 2010. Using transmitters as the index, a 255% growth was experienced between 1984 and 1994. Extrapolating this data from 1994 to 2010, a 100% increase in the number of units is projected. While improvements in technology are likely to reduce this value, it is clear from this data that the use of wireless will likely increase and that the increase will be dramatic. The figures below show actual data points (recorded by the FCC only up until 1994) and extrapolated data based upon a linear growth factor.

Year	Linear Projection of Transmitters	Actual Number of Transmitters
1984	317444	300231
1985	384240	364728

Figure 10

3.3. Empirical Model: Los Angeles County

The USAT task force decided that a specific urban area should be examined to determine the final spectrum requirement. Los Angeles County was chosen primarily because of its size and density of users.

The total number of utility employees for the county was obtained from United States Census data. From USAT survey data and previous market studies, a 66% voice radio penetration rate was applied to the employee count. Then, a 4% annual growth rate in voice radio usage was applied. As in the PSWAC study, wide band data and video projections were indexed on voice usage. From the USAT survey, it was determined that utility users would fall into the "heavy" usage category of both wideband data and video. This produced values of 27.33% of voice penetration for wide band data and 17% of voice penetration for video. Because these technologies are not yet mature, the penetration values were scaled back in the projection for the year 2000.

The amount of "current" spectrum available to utilities was subtracted from the "projected" spectrum requirements. The value for the current spectrum was calculated to be 2.24 MHz. The methodology for this calculation is included in Appendix A.

The spectrum projections were broken into three benchmark dates: 2000, 2004, and 2010. The projected spectrum requirements, less current power spectrum, are listed in the table below:

Year	2000	2004	2010
Bandwidth	1.0 MHz	1.9 MHz	6.3 MHz
Required			

The complete results of the Los Angeles projection are attached in Appendix B.

4. Conclusion

Utilities rely heavily on the use of private wireless systems for voice and data applications. The need for private wireless spectrum available to utility users will only increase as we transition from the twentieth to the twenty-first century. A total of 6.3 additional MHz will be needed by the year 2010. In addition to increased voice requirements, two other applications will increase the need for spectrum: wideband data and wireless video. These two developing technologies will play an increasingly important role in the operations of today's utility and the utility of the twenty-first century.

Appendix A: Methodology and Definitions

General Definitions

The formula used to calculate bandwidth was the PSWAC study equation, that is:

Erlangs Per Unit X No. of Units X SRC X 10

Required Bandwidth (MHz) = COD X Rate X Load X Reuse X (100-Error)

where:

Erlangs Per Unit: A measure of traffic load, or the time that the user transmits on a channel, expressed

as a ratio between 0.0 and 1.0. With 1.0 erlang the user transmits all the time and with 0.0 erlang the user never transmits. The Erlangs Per Unit is that factor

averaged over all of the transmitters being considered.

No. of Units: The number of transmitters within the geographic area being considered that are in

service over the time under consideration.

SRC (Kbps): The content of the source message to be transmitted is represented by the shortened

form SRC. All messages are in digital format, and the units are kbps, (kilo-bits-per-

second).

COD: This is a dimensionless factor of improvement in coding of the message into bits to

be transmitted. This improvement will take place between now and the date for

which the computation is made.

Rate (b/s/Hz): The rate at which data bits are transmitted over the air by the transmitter in each Hz

of its RF channel bandwidth. The units are b/s/Hz, (bits-per-second-per-Hz).

Load (%): The average percent of time that the channels are occupied by a transmission from a

user.

Reuse: The number of times the same RF channel is reused within the geographic area under

consideration.

Error (%): The average amount of error coding and overhead that is applied to the digitally

formatted message before transmission. With 0% coding there are no bits added to the message, and with 50% coding, half of the transmitted bits will be dedicated to

overhead, error mitigation and correction.

Current Spectrum Allocated to Power (IW) Users

The primary focus of this report was on Part 90 "mobile" spectrum. Consequently, the "current spectrum allocated to power users" was based entirely on channels allocated in Part 90. This assessment did not consider Part 101 "fixed" microwave spectrum.

To best gauge the amount of "IW" (power) spectrum, pre-refarming channels were analyzed. In the VHF/UHF bands, the bandwidths of the exclusive IW channels were added together to yield 0.565 MHz of spectrum.

800/900 MHz spectrum proved more difficult to evaluate because utilities do not have their own "pool" within the 800/900 MHz band, but rather are part of the more general Industrial/Land Transportation pool. To determine the amount of "utility" spectrum in this band, a 35-mile radius search was performed about the center of the City of Los Angeles for all Industrial/Land Transportation entities in the 800 and 900 MHz bands. These records were then analyzed to determine which licensees were utilities. After separating the utilities from the non-utilities and accounting for duplicate records, 1.68MHz of 800/900MHz utility spectrum was calculated.

Adding the VHF/UHF spectrum (0.565 MHz) to the 800/900 MHz spectrum (1.68 MHz) yielded the total current mobile spectrum available to utilities: 2.24 MHz.

Improved Future Technology

Future improvements in technology were addressed by the USAT model. As digital modulation and coding schemes become more sophisticated, wireless communication systems will be able to deliver more capacity per unit of electromagnetic spectrum (Hz). These improvements were addressed by the "rate" and "err" parameters in the model.

"Rate" is expressed in the units of b/s/Hz (bits-per-second-per-Hz), and is defined as the rate at which data bits are transmitted over the air by the transmitter in each Hz of its RF channel bandwidth. Clearly, as systems become more efficient, the rate will increase. Thus, there will be more bits-per-second for the same 1 Hz of bandwidth. Today, for example, a typical digital radio operating on 12.5 kHz channel, operates at a throughput of 9.6 kbps (e.g., 4.8 kbps VSELP added to 2.1 kbps Error Correction Coding and 2.7 kbps Embedded Signaling). 9.6 kbps divided by 12.5 kHz yields 0.768 kbps/kHz. This reduces to 0.768 bps/Hz. In the USAT model, the rate values .75 for voice and data and 2 for wideband data and video were employed for the year 2000. By 2010 these values increase to 1/1.5 and 3.5 respectively. The "err," or "error," parameter is defined as the average amount of error coding and overhead that is applied to the digitally formatted message before transmission. With 0% coding there are no bits added to the message, and with 50% coding, half of the transmitted bits will be dedicated to overhead, error mitigation and correction. This parameter will probably improve in future years. "Improvement" will yield a smaller value — less coding with greater throughput. In the USAT model, the err factor was set at 54% for the year 2000 and improved to 50% by the year 2010.
